Question Label : Short Answer Question

Consider a training set that contains 10 samples to train a neural network. Further, mini-batch GD algorithm has been chosen to update the parameters of the network with a batch size of 2. Suppose that we use an exponentially decaying learning rate scheme $\eta_t = 1.5 \exp(-\frac{t}{2})$ and train the model for 2 epochs. What will be the value of the learning rate η_t at the end of the training? Assume, t starts from zero.
Enter the answer to 3 decimal points (that is, if your answer is -0.12145, then enter it as -0.121)

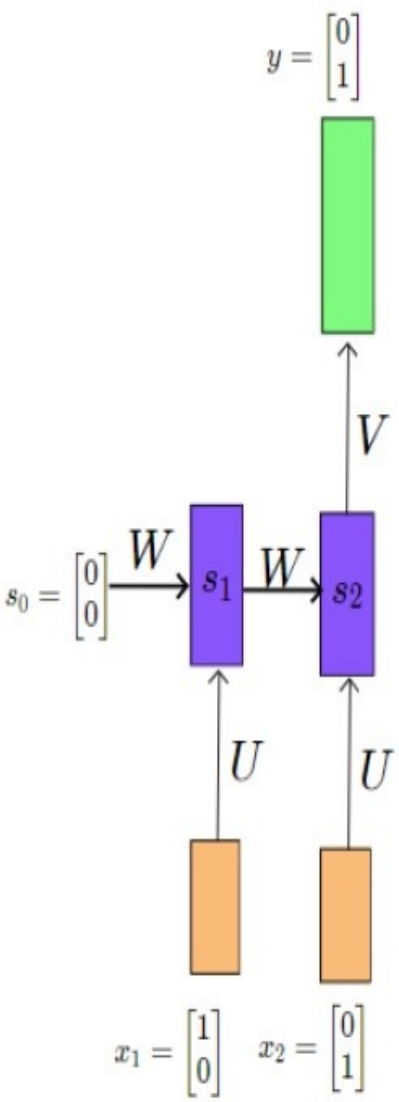
Consider a simple RNN for a binary sequence classification problem.



Suppose the weight matrices U, V, W are initialized as follows

$$W = U = V = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}$$

The state vector s_t is computed as follows

$$s_t = tanh(Ux_t + Ws_{t-1})$$

What is the loss value? Use cross entropy loss with natural logarithm. **Note**:In all your calculations, consider only the first two decimal places of any number (such as inputs, intermediate results..). That is, if the number is -1.0234, take it as -1.02.

Consider a fully connected feed forward neural network with 3 hidden layers. The weight matrix W_1 connecting the input layer to the first hidden layer is of shape 10×100, similarly the shape of other weight matrices are as follows $W_2 : 100 \times 50$, $W_3 : 50 \times 10$, and the weight W_4 connecting the final hidden layer and the output layer is of shape 10×3. The network solves the multi-class classification problem by using the cross entropy loss function.

Based on the above data, answer the given subquestions.

Question Label : Multiple Choice Question

The update rule for the ADAM (Adaptive Moments) optimization algorithm is given below,

$$m_t = \beta_1 m_{t-1} + (1-\beta_1)\nabla w_t$$
$$v_t = \beta_2 v_{t-1} + (1-\beta_2)(\nabla w_t)^2$$
$$w_{t+1} = w_t - \frac{\eta}{\sqrt{\hat{v}_t + \epsilon}}\hat{m}_t$$

Here, $0 \leq \beta_1 < 1$ and $0 \leq \beta_2 < 1$ and t starts from zero (that is, $t = 0, 1, 2, \cdots$). Both m_t and v_t are initialized to zero. However, the update rule uses the bias corrected version of m_t and v_t. Which of the following is the bias corrected version of m_t?

Helper:

$$m_t = (1-\beta_1)\sum_{\tau=0}^{t}\beta_1^{t-\tau}\nabla w_\tau$$

and assume that $E[\nabla w_\tau] = E[\nabla w] \quad \forall \tau$, if required.

Options :

6406532052244. ✖ $\hat{m}_t = \frac{m_t}{1-\beta_1^t}$

6406532052245. ✔ $\hat{m}_t = \frac{m_t}{1-\beta_1^{t+1}}$

6406532052246. ✖ $\hat{m}_t = m_t$

6406532052247. ✖ $\hat{m}_t = \frac{m_t}{1-t\beta_1^t}$

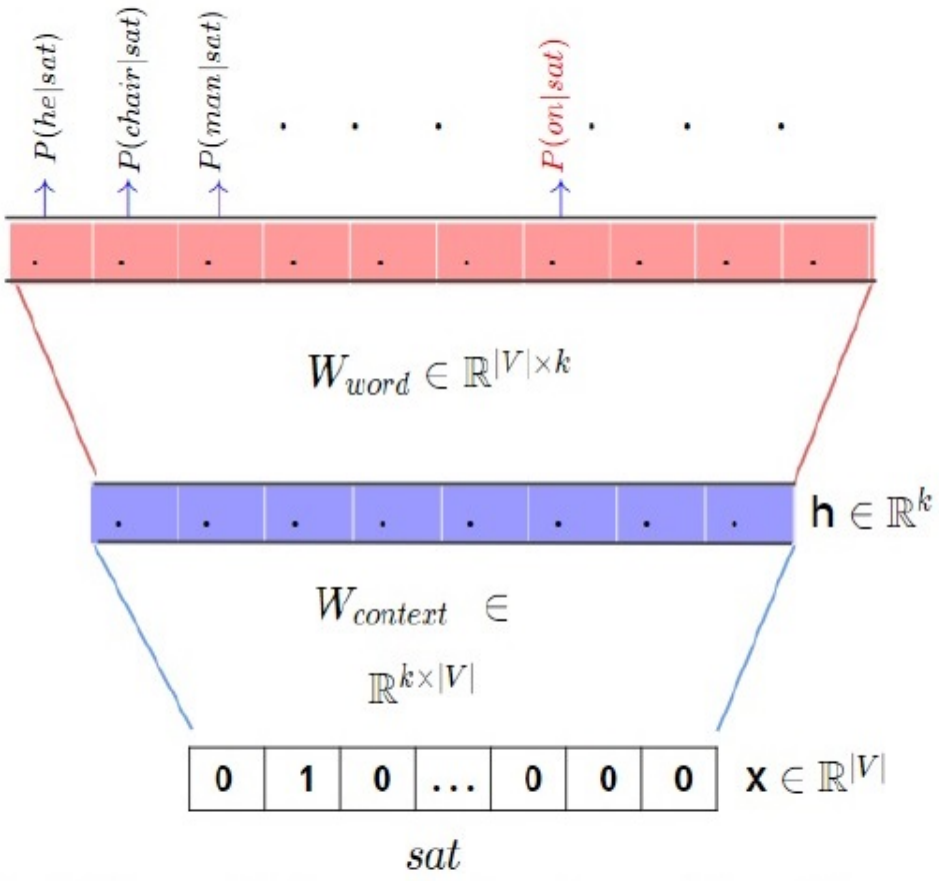
Question Numbers : (90 to 91)

Question Label : Comprehension

Consider a model shown below that learns the distributed vector representation of words by learning to predict the target word v_w given the context word u_c. Here, v_w and u_c are the vector representation of target word at index w of the output vocabulary and context word at index c of the input vocabulary, respectively.



In the diagram, $|V|$ denotes the size of the vocabulary, $W_{context}$ and W_{word} are learnable parameters. The vector representation for all context words are arranged as columns of $W_{context}$ and the vector representation for all target words are arranged as row vectors in W_{word}. The parameters are initialized randomly. The input x is one-hot-representation of a word in the input vocabulary. Assume that the size of both input and output vocabulary are equal.

Based on the above data, answer the given subquestions.

Sub questions
